Reliability

#### Abstract

Reliability is vital for ultra-reliability low-latency transmission applications in Industrial Wireless Networks (IWNs). The power-domain Non-Orthogonal Multiple Access (NOMA) technology can support multiple parallel transmissions, and has been thought of as one of the most powerful candidate radio access technology for the next-generation IWNs. However, it suffers from low transmission reliability because of the high interferences caused by parallel transmissions in power-domain NOMA. In this paper, given the real-time performance requirements, we consider a single-hop network supporting 2-Successive Interference Cancellation, and study how to maximize the reliabilities of uplink transmissions by the joint user pairing and power allocation. We show that the problem is solvable in polynomial time by an optimal algorithm with complexity of $\mathcal{O}(\quad)$, where is the number of users. The performance evaluations reveal that the transmission reliabilities will increase exponentially with the linear degradation of the guaranteed real-time performance.

## 1. Introduction

Communication reliability and transmission delay are two important performance metrics for applications in Industrial Wireless Networks (IWNs). Therefore, Ultra-Reliability Low-Latency Communications (URLLC) are considered as one of the key technologies for the next-generation IWNs [1]. In many applications in IWNs, low delay guarantee instead of low average delay is rigidly required, since outdated sensory data is of no meaning for some time-sensitive applications, such as the real-time controls in oil well exploiting [2]. Thus, media access technologies with high transmission reliability and the guaranteed real-time performance for uplinks are urgently required in IWNs.

In recent years, the power-domain non-orthogonal multiple access (NOMA) technology is utilized in IWNs [3

In all, BPSK based 2-SIC technology is valuable for URLLC applications in IWNs.

We focus on a typical IWN topology, where multiple users transmit data to a BPSK based 2-SIC sink. The focus of this paper is how to maximize the total uplink transmission reliability of all users, under the premise of the guaranteed real-time performances, by joint user pairing and power allocation [9].

We have proved that for the optimal solution to the problem, the user pairing strategy and the power allocation strategy are independent with each other. Therefore, the joint optimization problem can be converted into a two-stage optimization problem. In other words, we can still find an optimal strategy by a two-steps algorithm framework as follows; first, finding an optimal user pairing strategy, and second, finding an optimal power allocation strategy under the above optimal user pairing strategy.

Our technical contributions are summarized as follows. (1) A reliability model of power-domain NOMA transmission is elaborated. Specifically, the uplink transmission reliability of a BPSK-modulated NOMA system with multiple users and one sink is modeled, and thus a closed-form expression of transmission reliability, which is based on the average bit error rate of multiple users, is presented. (2) It is proved that the original problem can be decomposed into a two-stage optimization problem: namely, a multi-slot user scheduling sub-problem and a single-slot power allocation sub-problem, and the decomposition greatly reduces the complexity of problem solving. (3) For the single-slot power allocation sub-problem, an optimal power allocation strategy is designed. For the multi-slot user scheduling sub-problem, an optimal user grouping algorithm is designed. (4) Based on the theoretic foundation and the algorithms designed, a reliability-optimal algorithm with guaranteed delay is designed with complexity of $(\log ) \log )$.

This remainder of this paper is organized as follows. Section 2 is related works, and Section 3 elaborates the receiving model of signals from 2-SIC, which is the foundation of all theoretical analyses. Section 4 is the theoretic preliminaries of this paper. In Section 4.1, the closedform BER expression of two parallel users is proposed, which is the base for all lemmas and theorems in this paper. In Section 4.2, there are some theoretic preliminaries based on closed-form BER expression proposed in Section 4.1, and besides, the minimal BER of two users in one time slot is elaborated. The cases of three users in two slots and four users in four slots are deduced in Section 4.3 and Section 4.4, respectively. In Section 4.5, we propose an optimal allocation strategy for two parallel users, which is the base of user scheduling strategy. We start to deal with the reliable uplink transmissions problem in Section 5 as follows; Section 5.1 formulates the problem, and Section 5.2 figures out the independency between the power allocation and the user pairing, and then the optimal algorithm is introduced based on the independency. Section 6 is the performance evaluations, and the last section is the conclusions. The logic structure of this paper is also illustrated in Fig. 1 for clarity, where arrows depict theoretic dependencies. Besides, all notations in the paper are listed in Table 1 for convenience.

## 2. Related works

S. Loyka and etc. analyzed the reliability of NOMA for Multiple Input Multiple Output (MIMO) system [10], where the reliability was defined as the outage probability of transmissions. It presented a closedform expression for the probability of error-free transmissions. For the Rayleigh-fading multiple-antenna channels, Shen and etc. presented a reliability model for SIC system with BPSK modulation [11]. Both [10] and [11] are Vertical Bell Labs Layered Space Time (VBLAST) based system. Obviously, it was distinct from that in the power-domain NOMA based system, where there was only one antenna on the receiver. Dinh-Thuan and etc. analyzed the outage probability of energy harvesting NOMA in [12], and Kader and etc. analyzed the outage probability, and outage sum capacity of full-duplex NOMA in [13].

Fig. 1. Logic stucture of this paper.

Wang and etc. proposed a more fine-grained reliability model of 2-SIC decoder, where the probability of the partially successful decoding is considered [14]. Based on our reliability model where the case of the partially successful decoding is omitted, we, however, proposed a lowcomplexity reliability-optimal scheduling strategy. Comparatively, to balance the complexity and the optimality for downlink transmissions, Shi and etc. employed random grouping strategy [15]. In [16], the optimal user pairing strategy was proposed to minimize the aggregate transmitting power, however, the transmission reliability was not taken into considerations. Hina and etc. provided a framework to analyze multi-cell uplink NOMA systems in [17]. In [18], the author formulated a sum-throughput maximization problem and optimized minimum rate requirements of the users. Tasneem and etc. made the exact BER performance analysis for downlink NOMA system over Nakagami-m fading channels in [19]. Ferdi and etc. analyzed the BER performances of downlink and uplink NOMA in the presence of SIC errors over fading channels in [20].

Bin. $X$ and etc. presented closed-form expressions of the outage probability of each user for an uplink 2-user NOMA system [21]. Gyeongrae and etc. derive an exact closed form of the outage probability for each secondary destination in cognitive radio network, considering that the channel coefficients between the primary source and the secondary receiving nodes follow Rayleigh distribution [22]. Worawit and etc. proposed a power allocation scheme based on a deep learning approach for maximizing the sum rate for downlink NOMA system [23]. Aitong and etc. presented an outage performance of NOMAbased unmanned aerial vehicle assisted communication with imperfect SIC [24].

RFID has also enormous applications in enhancing the reliability of IWNs. A collaborative decoding method is proposed to overcome the low time-efficiency and the information corruption issue in range query of sensor-augmented RFID systems [25]. In [26], the hash-collision is utilized to support parallel transmissions from multiple RFID and it is obviously helpful for improving reliability of IWNs.

## 3. System models

We consider a network of single-hop, single channel wireless network consisting of single-antenna User Equipments (UEs) and a single-antenna sink. The sink is equipped with a BPSK-based 2-SIC receiver. A 2-SIC receiver can decode at most two signals in one time.

In the considered network, time is divided into frames, and a frame is divided into multiple time slots. The maximal transmit powers of all users are the same, and the transmit power is continuously adjustable. We only consider perfect interference cancellation, i.e., the residual error is zero, which has been widely adopted [27]. The channel gain

Table 1
Notations.

|  | Received signal at the sink |
| :---: | :---: |
|  | User |
|  | Channel gain of to the sink |
|  | Transmit power of |
| , | Transmitted symbols by Alice and Bob, , $\in\{1,-1\}$ |
|  | Normalized received amplitude of |
| Å | Maximum received normalized amplitude of |
| ( , ) | Bit error number when normalized received amplitudes of Alice and Bob are and |
| ( , ) | Bit error rate when normalized received amplitudes of Alice and Bob are and |
| $\cdot 1$ | argmin ( , ) given |
| $\sim 1$ | The minimum of , and $\AA$ |
|  | Frame length bound |
|  | Power of noise |
|  | The scheduled slot index for , $\in$ [1, ] |
| ( ) | Bit error numbers when and transmit simultaneously on slot |
| $((\quad=1) \mid(0,0))$ | The probability that the decoding symbol of is 1 , given both and transmit data bit 0 simultaneously |

actually characterizes the loss of signal power as the signal propagates through the channel from a user to the sink. We assume the channel gain keeps constant during the time span of a frame, which is suitable for slow-fading channels.

When two users, Alice and Bob, transmit to the sink at the same time, the received signal is as followed:

$$
\begin{equation*}
=\sqrt{ } \quad+\sqrt{ } \quad+_{0} \tag{1}
\end{equation*}
$$

where and are the transmitting powers of Alice and Bob. and are their channel gains. ${ }_{0}$ is the additive white Gaussian noise which obeys $\left(0,{ }^{2}\right)$, where ${ }^{2}$ is the power of noise, and are the symbols transmitted by Alice and Bob, respectively. When Alice transmits digital data ' 1 ', equals to 1 , it equals to -1 otherwise.

By normalizing , we get
$=-=\underline{\sqrt{ }}+\underline{\sqrt{ }}+$.

Definition 1. For user whose channel gain is , its normalized received amplitude is $=\sqrt{ }$ when its transmit power is.

The normalized received signal $=$ for in (1) is thus

$$
\begin{equation*}
=\quad+\quad+\underline{0} \tag{2}
\end{equation*}
$$

The normalized received signal $=$ thus follows the Gaussian distribution whose mean is $\quad+\quad$ and variance is 1. Because the BPSK signal is decoded by a zero-crossing detector, the decoding results of and $=$ are the same.

We assume that users have data to be transmitted, ${ }^{1}$ and the access delay of every user should be no larger than the time span of slots, where $\leq 2$ must be held.

In classic communication theory, the reliability of a transmission is measured by the expected Bit Error Rate (BER) of the transmission. Therefore, for parallel transmissions, it is reasonable that the transmission reliability is defined as the mean of their expected BERs in this paper.
${ }^{1}$ At the beginning of a frame, these users which have transmission tasks will report themselves to the sink via control channel. Since we only need to find the users which try to be transmitters of the upcoming frame, method based on compressive sensing, can achieve the goal with low overhead [28].

Fig. 2. The error intervals of and for transmitting ( 0,0 ).

Fig. 3. The error intervals of and for transmitting ( 0,1 ).

## 4. Preliminary and analysis of two parallel users

This section provides some preliminaries. We first present an explicit closed-form expression of BER for BPSK based 2-SIC receiver in Section 4.1. Then, we present the optimal power allocation and scheduling strategy for two parallel users in Section 4.2. Besides, some associated inferences are introduced in Sections 4.3 and 4.4. They also lay theory foundations for finding an optimal algorithm with low complexity. The optimal power allocation for two parallel users is proposed in Section 4.5.

### 4.1. Closeform BER expression of two paralled users

Two users, and , are assumed to transmit simultaneously. Besides, all symbols are assumed to have equal probability of occurrence, which is usually admitted after source coding.

The normalized received amplitude of is , and that of is and we suppose $>$. According to the principle of SIC decoder, will be decoded first.

When both and transmit data ' 0 ', as shown in Fig. 2, based on the presumption of Gaussian distribution of noise power and the principle of BPSK decoders, the decision interval for to be +1 is $(0, \infty)$, and the decision interval for to be +1 is $(-, 0)$ if decodes correctly. Therefore, the error probability of determining is

$$
((\quad=1) \mid(0,0))=\frac{1}{\sqrt{2}} \int_{+}^{\infty}-\frac{2}{2}=(+)
$$

, where (.) denotes function which is defined as ( ) $=\frac{1}{\sqrt{2}}$ $\int^{\infty}-\frac{2}{2}$, and $(0,0)$ means that both and simultaneously transmit data ' 0 '.

Only when the symbol from is decoded successfully, that of can be correctly decoded. Therefore, the error probability of determining provided is decoded correctly is

$$
\begin{aligned}
&((=1) \mid(\quad=-1) \&(0,0))=\frac{\frac{1}{\sqrt{2}} \int^{+}-\frac{2}{2}}{\frac{1}{\sqrt{2}} \int_{-(+)^{-\frac{2}{2}}}^{\infty}} \\
&=\frac{()-(+)}{(-(+))} .
\end{aligned}
$$

$((=1) \mid(\quad=-1) \&(0,0))$ is the probability that symbol of is decoded as 1 , given that (1).symbol of has been decoded as -1 ; (2).both and transmit data bit 0 simultaneously. Similarly, when both and transmit data ' 1 ', we get

$$
\begin{aligned}
& (=-1 \mid(1,1))=(=1 \mid(0,0)) \\
& ((=-1) \mid((=1) \&(1,1)))=((=1) \mid(=-1) \&(0,0)) .
\end{aligned}
$$

The above related equations reveal some probabilities in decoding when Alice and Bob transmit same data simultaneously. Similarly, we present some probabilities in decoding when distinct data are transmitted parallel.

As shown in Fig. 3, where transmits ' 0 ' and transmits ' 1 ', the decision interval for to be +1 is $(0, \infty)$, and the decision interval for to be -1 is ( $-\infty,-\quad$ ) if decodes correctly. Therefore,

$$
\begin{aligned}
& ((=1) \mid(0,1))=\frac{1}{\sqrt{2}} \int_{-}^{\infty}-\frac{2}{2}=(-) \text {, } \\
& ((\quad=-1) \mid((=-1) \&(0,1)))=\frac{\frac{1}{\sqrt{2}} \int^{\infty-\frac{2}{2}}}{\left.\frac{1}{\sqrt{2}} \int_{-( }^{\infty}-\right)^{-\frac{2}{2}}} \\
& =\frac{()}{(-(-\quad))} \text {. } \\
& \text { Similarly, }((=-1) \mid(1,0))=((=1) \mid(0,1)) \text {, and } \quad((= \\
& \text { 1) } \mid((=1) \&(1,0)))=((\quad=-1) \mid((=-1) \&(0,1))) \text {. } \\
& \text { So the expect of the error bit number }((,)) \text { is } \\
& (\quad(,))=((=1) \mid(0,0))+((=1) \mid(0,1))+ \\
& \frac{((=1) \mid((=1) \&(1,0))) \quad((=1) \&(1,0))}{2}+ \\
& \frac{((=1) \mid(\quad=-1) \&(0,0))((=-1) \&(0,0))}{2}
\end{aligned}
$$

and thus average of the two users' BERs is

$$
=\frac{(,)=\frac{1}{2}((,))}{(1)+(-)+\frac{1}{2}(+)} .
$$

Based on the above closed-form expression, we can now present some characteristics of ( , ).

### 4.2. Preliminary and minimal BER of two users in one slot

Lemma 1. ( , ) is a decreasing function of
Proof. The lemma is obvious because

$$
\frac{(,)}{}=\frac{1}{2 \sqrt{2}}\left(--\frac{(-)^{2}}{2}-\frac{1}{2}-\frac{(+)^{2}}{2}\right)<0 .
$$

Lemma 1 reveals that the firstly-decoded signal should be in its maximal power for achieving minimum BER. Next, Lemma 2 shows that the optimal power of is unique if the power of is given.

Lemma 2. For any given value for , if $\geq \sqrt{5}$, there is a unique value for , which is notated as . , such that ${ }_{\text {I }}=\operatorname{argmin} \quad($, ).

Proof. The partial derivative of is

$$
\begin{equation*}
\frac{(,)}{2 \sqrt{2}}=\frac{1}{\left.\left.--\frac{2}{2}+-\frac{(-)^{2}}{2}-\frac{1}{2}-\frac{(+)^{2}}{2}\right)\right) ~\left(-\frac{1}{2}\right)} \tag{4}
\end{equation*}
$$

For a given , let ()$=(\quad$, ) Obviously, it is a monotonically increasing function of . Besides, it can be easily verified that $\quad(0)=\frac{1}{2 \sqrt{2}}\left(-1+\frac{1}{2}-\frac{2}{2}\right)<0$, and $\quad(\quad)=\frac{1}{2 \sqrt{2}}\left(1-\frac{1}{2}-2^{2}-\right.$ $\left.\frac{-2}{2}\right)>0$ if $\geq \sqrt{5}$. Based on the well-known mean value theorem for monotonic functions, there is one and only one value . for , where.$<$, such that $()=$.0 . In other words, when
$0 \ll \quad<\quad, \quad(, \quad)$ is a decreasing function of. When $>, \quad, \quad, \quad$ is an increasing function of .

Based on the above proof of Lemma 2, if . is achievable, .. is obviously the theoretically optimal ${ }^{2}$ received amplitude of the seconddecoded user when the received amplitude of the first-decoded user is
. Further, we list two mathematical properties for . , which are vital to the proof of Lemma 6 below.

Lemma 3. For given , the theoretical optimal received amplitude of the second-decoded user is denoted by . . Then, . is an increasing function of if $\quad{ }_{\text {, }}>1$.

Proof. See in Appendix A.
Lemma 4. $-\quad>1$ for any $\geq \sqrt{5}$.
Proof. See in Appendix B.
Based on the conclusions of this subsection, we have some inferences in the following two subsections, and these inferences are essential for an optimal algorithm with low complexity.

### 4.3. Minimal BER of three users in two slots

A note which will be frequently used in the remainder of this paper is as follows, if both and monopoly a slot, their average BER is denoted by ( ; ), where

$$
\begin{equation*}
(;)=\frac{()+()}{2} \tag{5}
\end{equation*}
$$

Lemma 5 below reveals the reliability-optimal user pairing strategy for three users.

Lemma 5. For thre users, , and , if their normalized received amplitudes satisfy $\gg$, the following inequalities hold. ${ }^{3}$
(1) $\quad(, \quad ;)<\quad(, \quad ; \quad$,
(2) $\quad(, \quad ; \quad<\quad(, \quad ; \quad$.

Proof. Based on (3) and (5), ( , ; ) = $\frac{1}{3}(\quad()+(-\quad)+$ $\left.\frac{1}{2}(+)+()\right), \quad(, \quad ; \quad)=\frac{1}{3}\left(()+(-)+\frac{1}{2}(+\right.$
$)+())$, and $\quad\left(, \quad ; \quad=\frac{1}{3}\left(()+(-)+\frac{1}{2}(+\right.\right.$
$)+())$.
Let ${ }_{1}()=\frac{1}{3}(()-(-\quad+))$, therefore, $\quad, \quad()=\frac{1}{3}\left(--\frac{2}{2}+\right.$ $\left.-\frac{(+-)^{2}}{2}\right)<0$ since $>$. $(, \quad ; \quad)-\quad(\quad ; \quad)={ }_{1}(-)-{ }_{1}()+\frac{1}{2}(1+$
$)-(+))$. On one hand, $(+)-(+)>0$ since ( $)$ is a decreasing function. On the other hand, ${ }_{1}(-\quad)-{ }_{1}(\quad)>0$ since ${ }_{1}^{\prime}()<0$. So, $\quad(\quad, \quad$ ) $<\quad(, \quad ; \quad$.
Let ${ }_{2}()=\frac{1}{3}(()-(-\quad+))$, therefore, ${ }_{2}^{\prime}()=\frac{1}{3}\left(-\frac{2}{2}+\right.$ $\left.-\frac{(+-)^{2}}{2}\right)<0$ since $>{ }^{2}, \quad(, \quad ; \quad-\quad(, \quad ;)=$ $\frac{2(-)-2(+)}{2}+\frac{(-1-i-1}{2} \cdot 2(-\quad)-2(-\quad)>0$ since $\left.{ }_{2}^{2}{ }^{2}\right)<0$. $(-)-{ }^{2}(-)>0$ since () is a decreasing function. So, ( , ; ) < ( ; ).

[^0]

Fig. 4. Convexity of ${ }_{1}()$.

### 4.4. Minimal BER of four users in two slots

Lemma 6 below reveals the reliability-optimal user pairing strategy for four users.

Lemma 6. Four users, , and ,
 holds. ${ }^{4}$
(2) if ther normalized received amplitudes satisfy $\ggg$, then $(, \quad ; \quad)<\quad(, \quad$, $)$ holds.

Proof. $\quad(, \quad ; \quad)=\frac{1}{4}\left(()+(-)+\frac{1}{2}(+)+\right.$ ()$\left.+(-)+\frac{1}{2}(+)\right)$,
$(, \quad ; \quad)=\frac{1}{4}\left(()+(-)+\frac{1}{2}(+)+()+\right.$
$\left.(-)+\frac{1}{2}(+)\right)$,
$(, \quad ; \quad, \quad)=\frac{1}{4}\left(()+(-)+\frac{1}{2}(+)+()+\right.$ $\left.(-)+\frac{1}{2}(+)\right)$.
(1) Let ${ }_{1}()=\frac{1}{4}(()-(-\quad+)),{ }_{1}()$ and ${ }_{1}^{\prime \prime}()$ are the firstorder and the second-order derivatives of ${ }_{1}()$, respectively, then ${ }_{1}()=$
 Further, let $h()=-\frac{2}{2}$, then ${ }_{1}^{\prime \prime}()=\frac{1}{2}(h()-h(+\quad-\quad))$. Obviously, $h()$ is a decreasing function when $\in[1, \infty)$, and ${ }_{1}^{\prime \prime}()>0$ when $\in[1, \infty)$, i.e., 1 ( ) is convex in $[1, \infty)$. Based on Lemma 4, $-. \quad>1$ since $>\sqrt{5}$. Besides, since,$>$ based on the prerequisite of Lemma 6, $\quad$. $\quad$. So, ${ }_{1}()$ is convex for $\in[-\infty)$.
 one hand, ${ }_{1}\left({ }^{2}\right)-{ }_{1}(-)>0$ since ${ }_{1}()<0$ for any . On the other hand, just as shown by Fig. 4, since ${ }_{1}()$ is convex for $\in[-, \infty){ }_{1}(-)+{ }_{1}(+)>{ }_{1}(-)+{ }_{1}(+)$. Thus, $\quad(, \quad ; \quad)<(, \quad$, $)$.
(2) Let $2_{2}()=\frac{1}{4}(()-(-+))$, therefore, ${ }_{2}^{\prime}()=-{ }^{\frac{2}{2}}+$ $-\frac{(+-)^{2}}{2}<0$.

$$
\begin{aligned}
& \text { ( , ; , )- ( ; , ) = } 2(-1)-{ }_{2}(1)+ \\
& \left.2(-)^{\prime}+\frac{1}{2}\left(2_{2}^{\prime} \prime^{\prime}+\right)-2^{\prime}+\right)^{\prime} . \\
& 2(-)-2()>0 \text {, and } 2(+)-2(+)>0 \text {, since } \\
& { }_{2}^{\prime}()<0 \text {. } \\
& \text { Thus, ( , ; ) < ( , , ). }
\end{aligned}
$$

[^1]
### 4.5. Optimal power allocation for two paralle users

Based on the above results of the closed-form BER expression (3), the optimal power allocation strategy for two parallel users is derived in the following subsection. Note that $\quad()=(-)^{2}$, which computes the transmitting power of if its received amplitude at the sink is .

Lemma 7. Assume that the maximal normalized received amplitudes of two paralle users and are $\AA$ and $\AA$, respectively. If is decoded firstly, the minimal BER is achieved only when transmits with its maximal power
( $\AA$ ), and the transmit power of is ( $\left\{{ }_{\mid,}, \AA\right\}$ ) at the same time

Proof. The proof can be got directly based on Lemmas 1 and 2 as follows. According to Lemma 1, the firstly-decoded signal should be transmitted in its maximal power for achieving minimum BER. According to Lemma 2, the optimum is achieved when transmits with power $\quad\left({ }_{\| \AA}\right)$ if ${ }_{\cdot \mid \AA} \leq \AA$. On the contrary, if ${ }_{\| \AA}>\AA$, should transmit using its maximal power, i.e., $(\AA)$.

In the remainder of this paper, $\left\{,{ }_{\|}, \AA\right\}$ is denoted by ${ }^{\sim}{ }_{\mid \AA}$ for short.

Based on Lemma 7, the theoretically minimum $B E R$ is $\left.(\AA, \tilde{\AA})=\frac{1}{2}(\tilde{l} \mid \AA)+(\AA-\tilde{\sim} \mid \AA)+\frac{1}{2}(\AA+\tilde{A} \mid \AA)\right)$.

Lemma 7 is for determining the optimal transmit powers of two parallel users, given their decoding order. The next lemma reveals the best decoding order for two parallel users.

Lemma 8. For two parallel users and with their channel gains being and , respectively, if they have the same transmit power bound and $>$. The minimum BER can be achieved only when is decoded firstly.

Proof. Since and have the same maximal transmit power and $>\quad$, we have $\AA$ < $\AA$.
If is decoded firstly, according to Lemma 4, the minimum BER is $\left(\AA,{ }_{i}, \AA\right)$.

Otherwise, if is decoded firstly,
(1) if $\AA>{ }_{\|} \AA$, the optimal BER is thus $\left(\AA,{ }_{\sim} \AA_{\AA}\right)$ based

 ( $\AA, \cdot{ }_{\|} \AA$ ).
(2) if $\AA \leq, \mid \AA$, the optimal BER is thus $(\AA, \AA)$ based on Lemma 7. Based on Lemma 1, $(\AA$, $\mid \AA)>\quad(\AA$, $\mid \AA)$. Based on Lemma 2, $(\AA, \mid \AA) \geq(\AA, \AA)$ if $\AA \leq{ }_{\cdot} \AA$. Thus, $(\AA, \mid \AA)>\quad(\AA, \AA)$.
In conclusion, the minimum BER can be achieved only when is decoded firstly.

## 5. Problem formulation and solving

In this section, The problem of reliable uplink scheduling with guaranteed real-time performance for Users is formulated. To solve it, Lemma 9 reveals that all provided slots should be utilized, which is the foundation. In Theorems 1 and 2, the optimal scheduling strategies for three and four users with two time slots are given, respectively. Then the general case, i.e., the scenario of users in time slots, is solved by Algorithm 1. and its optimum is proven by Theorem 3.

### 5.1. Problem formulation

Definition 2. Reliable Uplink Scheduling for 2-SIC (RUS-2SIC). We are given a single-hop network consisting of a sink equipped with a perfect BPSK-based 2-SIC receiver and users $1,2, \ldots$, whose channel gains are $1,2, \ldots$, , respectively. Without loss of generality
(W.I.o.g.), we assume $1 \geq 2 \geq \cdots \geq$, the maximal transmit powers of users are same, and noise power is 0 for all users. Denote their transmit powers to be ${ }_{1}, 2, \ldots$, , respectively. Assign transmit powers to and schedule the users such that the average BER of the users is minimized under the following constraints: (1) Every user is scheduled only once in a frame. (2) The frame length is no larger than the given value .

The RUS-2SIC can be formulated as follows.

$$
\begin{align*}
& \min _{\substack{\{1,2, \ldots, j \\
1,2 \ldots,\}}}=\sum_{=1} \sum_{\substack{G 1, \ldots,\}  \tag{6a}\\
\in, \ldots, j}} \text { () }  \tag{6b}\\
& ()=\left\{\begin{array}{llll}
(,) & (=1 & = \\
(,) & (=) & (\neq) \\
( & (\neq) & (\neq) \\
0 & & (\neq) & (\neq)
\end{array}\right.  \tag{6c}\\
& \text {.. } 0 \leq \sum_{=1} 1(=) \leq 2 \quad \forall \in[1,]  \tag{6d}\\
& \in\{1, \ldots,\} \quad \forall \in[1,]  \tag{6e}\\
& =\underline{\sqrt{ }} \quad \forall \in[1,] \text {, }
\end{align*}
$$

where is the scheduling slot index for , $1($.$) is the indication func-$ tion. Obviously, the system reliability is influenced by both $\left\{_{1}, 2, \ldots\right.$, \} and $\left\{{ }_{1}, 2_{2}, \ldots,\right\}$. is the frame length bound, which is for gauging the real-time performance. ${ }^{5}$

### 5.2. Problem solving

It seems that RUS-2SIC is a joint optimization problem, and thus high time complexity will be inevitable if it is solved by the optimization-based algorithms. We, however, propose a low-complexity algorithm. To clearly explain the idea of the algorithm, we present two key attributes of the optimal user pairing strategy, i.e., Theorems 2 and 3. Then we propose an optimal scheduling strategy based on the two key attributes, and prove its uniqueness.

Lemma 9. If $\leq \leq 2$, for the optimal solution to RUS-2SIC, there is no idle slot.

## Proof. See in Appendix C.

Lemma 9 is vital although intuitive, and it is the foundation of the optimal strategy. The next two theorems reveal the optimal user pairing strategy between any two slots, and the two theorems are a key criterion for the optimal user pairing strategy of RUS-2SIC.

Theorem 1. For three users ${ }_{1}, 2,3$, whose maximum normalized re ceived amplitudes satisfy $\AA_{1}>\AA_{2}>\AA_{3}$, if they are assigned to two slots, the optimal user pairing will be $\left.\left\{\begin{array}{ll}\{1, & 3\end{array}\right\},\left\{{ }_{2}\right\}\right\}$, i.e, ${ }_{1}$ shares a slot with ${ }_{3}$, and ${ }_{2}$ monopolizes the other one.

Proof. There are obviously three pairing candidates: ${ }_{1}=\left\{\begin{array}{ll}\left\{\begin{array}{l}1\end{array}\right. & 3\end{array}\right\}$; $\{2\}\},{ }_{1}=\left\{\left\{2_{2}, 3\right\} ;\left\{_{1}\right\}\right\}$ and $\left.\left.1=\left\{\begin{array}{ll}1,2 & 2\end{array}\right\} ;{ }_{3}\right\}\right\}$. By comparing their optimal BERs directly, ${ }_{1}$ can be proven to be optimal as follows.

Due to Lemma 5, Lemmas 7 and 8, the optimal amplitude assignment for ${ }_{1}$ is $\left\{\left\{\AA_{1}, \tilde{S}_{3} \mid \AA_{1}\right\} ;\left\{\AA_{2}\right\}\right\}$, and these for ${ }_{1}$ and ${ }_{1}$ are $\left\{\left\{\AA_{2} \tilde{\prime}^{\prime} 3 \mid \AA_{2}\right\} ;\left\{\AA_{1}\right\}\right\}$ and $\left\{\left\{\AA_{1}, 2 \mid \AA_{1}\right\} ;\left\{\AA_{3}\right\}\right\}$, respectively.
(1) Comparing the optimal ${ }_{1}$ of ${ }_{1}$ with that of ${ }_{1}$.

Since $\AA_{1}>\AA_{2}>{ }^{\sim}{ }_{3 \mid} \AA_{2}$, due to Lemma 5, $\left(\AA_{2},{ }_{3 \mid} \AA_{\AA} ; \AA_{1}\right)>$

$$
\left(\AA_{1}, \tilde{N}_{3 \mid \AA_{2}} ; \AA_{3}\right) \text {. Due to the optimum revealed by Lemma } 7 \text {, }
$$

[^2]$\left(\AA_{1},{ }_{3} 3 \mid \AA_{2} ; \AA_{3}\right) \geq \quad\left(\AA_{1},{ }_{3 \mid} \AA_{1} ; \AA_{2}\right)$. Thus, as to the reliability, $\quad 1$ is better than ${ }_{1}$.
(2) Comparing the optimal of ${ }_{1}$ with that of ${ }_{1}$.

If ${ }_{| | \AA_{1}} \geq \AA_{3}$, the optimal amplitude assignment for ${ }_{1}$ is $\left\{\left\{\AA_{1}, \AA_{3}\right\}\right.$; $\left.\left\{\AA_{2}\right\}\right\}$. Due to Lemma 5, $\quad\left(\AA_{1},{ }_{\sim}^{2} \mid \AA_{1} ; \AA_{3}\right)>\quad\left(\AA_{1}, \AA_{3} ; \tilde{\sim}_{2 \mid \AA_{1}}\right)$ since $\AA_{1}>{ }^{\sim}{ }_{2 \mid \AA_{1}}>\AA_{\sim}$. Due to Lemma 1, $\quad\left(\AA_{1}, \AA_{3} ; \tilde{Z}_{2 \mid \AA_{1}}\right) \geq$ $\left(\AA_{1}, \AA_{3} ; \AA_{2}\right)$ since ${ }_{2 \mid \AA_{1}}^{\sim} \leq \AA_{2}$. Thus, $\quad\left(\AA_{1},{ }_{2 \mid} \AA_{1} \AA_{1} ; \AA_{3}\right)>$

Fig. 5. Optimal user pairing strategy.
is where $\in(/ 2$,$] . Otherwise, any other pairing strategy must be$ contradicted with either Theorems 2 or 3.

To describe the above example formally, the reliability-optimal low-complexity algorithm for RUS-2SIC as follows.

```
Algorithm 1. An optimal algorithm for RUS-2SIC \{
Input: : users set; [ ]: channel gains of users to the sink; :
noise power; :maximum transmission power; : guaranteed
delay; Å: max received amplitude of each user
Output: [ ]: optimal user pairing method; : optimal
power allocation
1. sort users in descending order of their channel gains to
the sink, and w.l.o.g., assume
    []\(\geq \quad[+1],(=1,2, \ldots,-1) ; 2 . \quad=\varnothing\)
3. \(\operatorname{for}(=1 ; \leq ;++) \quad \AA[]=\frac{\sqrt{ } \times[]}{0}\); // compute the
maximal normalized received amplitude of each user
4. for ( \(=1 ; \leq ;++\) ) \{ //designate the optimal strategy
5. if \((\leq-) \quad[]=\langle,+\rangle ;\)
else []\(=\{\);
6. for ( \(=1 ; \leq ;++\) ) \(\{/ /\) assign transmitting powers
7. if \((\leq-)\)
    []\(\left.=\quad ; \quad[+]=\AA 2\left(\quad\left\{\quad{ }_{\mid \AA[ }\right], \AA[+]\right\}\right) ; / /\) The
power allocation of User and User + in the th slot
8. else \{ [ ] = ;
```

We have a simple explanation for Algorithm 1 as follows. We first sort all users by their channel gains to the sink, then we calculate their maximum received amplitudes possible. Just as that illustrated in Fig. 5, line 4 and line 5 directly designate the optimal user pairing slot by slot. In line $5,\langle,+\rangle$ implies that and + share a slot, and will be decoded firstly, ${ }^{6}$ and \{ \} implies that monopolies a slot. ${ }^{7}$ From line 6 to line 8, we assign transmitting power for every user, where $\AA 2()$ is to compute the transmit power if its normalized received amplitude is , and $\left.{ }_{\cdot} \mid \AA \AA_{[ }\right]$is the theoretical optimal normalized received amplitude of + since and + share a slot and is decoded firstly.

Theorem 3. Algorithm 1 outputs an optimal solution to RUS-2SIC.
Proof. We prove it by contradictions. If there is another strategy differing from that output by Algorithm 1, there must be two user pairings, which occupy two slots and disobey the necessary condition for the optimality. Specifically, if both of them are full slots, then it disobeys Theorem 2. If one is a full slot and the other is a half-full slot, then it disobeys Theorem 1. In all, we cannot find a better user pairings strategy than that output by Algorithm 1.

A prominent merit of Algorithm 1 is its low complexity of $\mathcal{O}(\log )$ $\log$, which is mainly caused by the sorting algorithm at line 1.

[^3]| 15 | 1 | 1 | 1 | 1 | 1 | 1 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 20 | 25 | 30 | 35 | 40 | 45 | 50 |

Fig. 6. Average BER with users and delay bounds.

## 6. Performance evaluations

We evaluate the relationship between the transmission reliability and the delay bound by simulations in the first step. Fig. 6 illustrates the relationship among the average BER, the delay bound and the user number. Some simulation parameters are as follows: all users are deployed randomly in a ring area with the internal radius and the external radius to be 500 and 1200 respectively, and a sink is located at the center of the ring. The noise power is -126 , which the power spectral density is -173 / , while the bandwidth is 50 kHz . The maximum transmitting power is 16 for all users. The channel gain model is $=-20 \quad()-26 \quad()+19.2$ where $\quad$ is the channel gain, is the distance to the sink, and is 5 GHz .

How to set the parameter of the real-time performance, i.e., in formula (9), is vital for delay guarantee. Using the time span of a slot as the basic time unit, we assume that the data collection cycles of all users are the same, which are denoted by . The maximal delay bound is assumed to be , which is the real-time performance bound. Obviously, only if $2 \leq \leq$ holds, the real-time performance of every user will be guaranteed. Therefore, $L$ /2 $\rfloor$ is the maximal value for to guarantee the delay performance. Further, if $\leq 2$, every user will be given a transmitting opportunity in a frame. Therefore, the real-time performance is always guaranteed.

In Fig. 6, we can find that for a given user number, the average BER decreases exponentially with the increase of delay bound. In other words, the transmission reliability is greatly influenced by the realtime performance requirements. The reason is as follows. Given more relaxed real-time performance, more half-full slots will come into being in the optimal strategy generated by Algorithm 1. Since the average BER of a half-full slot is in general far less than that of a full slot, the transmission reliability thus increases. With the same delay bound requirement, the average BER always increases with the increment of the user number. The reason is also due to the fact that the increase of user number results in less half-full slots. Besides, we note that there is a sharp knee point at the end of each curve in Fig. 6. Indeed, it is virtually the orthogonal multiple access transmissions, where every user monopolies one slot.

Using the same simulation parameters, we compare the running time of Algorithm 1 with that using the Edmond s blossom method. On our personal computer with i7-4710HQ CPU and 16GB memory, their running times are illustrated in Fig. 7. Obviously, both of them grow rapidly with the user number. For any given parameter, the running time of Algorithm 1 is less by three orders of magnitude of that utilizing the Edmond' s blossom method. The reason is obvious because the complexity of Algorithm 1 is only $\mathcal{O}(\log )$, while that utilizes the Edmond's blossom method is $\mathcal{O}\left({ }^{4}\right)$.

Fig. 7. Comparison of algorithms' running time.

## 7. Conclusions

In this paper, we analyze the transmission reliability with guaranteed real-time performance for NOMA-based uplink IWNs. We formulate the problem and present an optimal algorithm. The complexity of algorithm 1 after sorting is actually ( ). The lowest complexity of sorting is quicksort whose complexity is ( $\log$ ). So, the overall complexity is ( $\log$ ) including the sorting process. The Both theoretical proofs and performance evaluations validate the optimality of the algorithm proposed.

Transmission reliability is a vital metric for IWNs because reliabilities are always rigidly required in industrial applications. Since powerdomain NOMA is now a powerful candidate media access technique for the next-generation IWNs, finding rapid algorithms for high-reliability communications are indispensable. Our research results lay a theoretical foundation for high-reliability low-latency transmissions for the next-generation IWNs.

## Appendix A. The proof of Lemma 3

$$
\begin{array}{r}
\text { Based on (4), for and } \quad \text {, , we have } \\
--\frac{\cdot^{2}}{2}+-\frac{(-\cdot)^{2}}{2}-\frac{1}{2}-\frac{(+\cdot \cdot)^{2}}{2}=0 \tag{7}
\end{array}
$$

In other words, can be seen as a function of $\quad$, . Therefore, $\frac{}{{ }_{l}}=$

$$
\begin{align*}
& \frac{\cdot)^{-\frac{\cdot^{2}}{2}}+(-\cdot)^{-\frac{(-\cdot)^{2}}{2}}}{(-)^{-\frac{(-\cdot)^{2}}{2}}-\frac{1}{2}(\cdot+)^{-\frac{(+\cdot 1)^{2}}{2}}} \\
& +\frac{\frac{1}{2}(\cdot+)^{-\frac{(\cdot+)^{2}}{2}}}{(-\ldots)^{-\frac{(-\cdot)^{2}}{2}}-\frac{1}{2}(\cdot \mid+)^{-\frac{(+\cdot)^{2}}{2}}} \tag{8}
\end{align*}
$$

Next, we aim to reveal that . always increases with , i.e., $\square_{\|}>0$. Since the numerator of (8) is larger than 0 because $>$ , , the sign of $\quad$._ totally depends on that of its denominator of (8).

Let ()$=-\frac{2}{2}, \in(0, \infty)$. Obviously, $\quad()=-\frac{2}{2}-2-\frac{2}{2}$. Thus ( ) increases with $\in(0,1)$, and decreases with $\in[1, \infty)$. Now the denominator of (8) can be rewritten as $\left(-\|_{1}\right)-\frac{1}{2}\left(+I_{1}\right)$. So, as long as $(-,) \in(1, \infty), \quad+\quad>1$, and thus $2(-$ $.1)-(+. \mid)>\left(-{ }_{\|}\right)>0$ because $>._{1}$. In other words, $\quad$ is an increasing function of if $-\quad . \quad>1$.

## Appendix B. The proof of Lemma 4

We prove it by contradictions. Assume that $\quad \quad_{\cdot} \leq 1$. According to (7),

$$
\begin{equation*}
-\frac{(-\cdot 1)^{2}}{2}=-\frac{(\cdot 1)^{2}}{2}+\frac{1}{2}-\frac{(+\cdot \mid)^{2}}{2} \tag{9}
\end{equation*}
$$

Since $\quad>\sqrt{5}$, the left part of (9) is thus $-\frac{(-\cdot)^{2}}{2} \geq-\frac{1}{2}=$ 0.6065 , while the right part is thus $-\frac{(\cdot 1)^{2}}{2}+\frac{1}{2}-\frac{(+\cdot 1)^{2}}{2} \leq-\frac{(\sqrt{5}-1)^{2}}{2}+$ $\frac{1}{2}-\frac{(2 \sqrt{5}-1)^{2}}{2}=0.4671$. So it brings contradiction to (9).
, the normalized received amplitude of a signal, is in fact the square root of the signal-noise ratio of the first-decoded signal at the receiver side. Although $>\sqrt{5}$ is required for this paper, the condition is generally true in practice. ${ }^{8}$

## Appendix C. The proof of Lemma 9

If there is an idle slot, there is at least one slot which includes two users. W.l.o.g., assume the two users are and , and $>$. Thus, their maximal normalized received amplitudes satisfy $\AA>\AA$.

According to Lemmas 7 and 8, for the two parallel users, their average optimal BER is $\quad\left(\AA \sim, \AA_{\Omega}\right)=\frac{1}{2}(\tilde{( } \mid \AA)+(\AA \sim \tilde{\AA})+$ $\frac{1}{2}(\AA \AA \tilde{+} \quad \mid \AA$ )).

However, if and monopoly a slot respectively, the optimal average BER of them is $\frac{1}{2}((\AA)+(\AA))$. Since () is a decreasing function of and ${ }^{\sim} \AA<\AA, \quad(\AA, \quad, \AA)>\frac{1}{2}((\AA)+(\AA))$. In other words, a smaller average BER can be got, which contradicts the assumption of the optimality.

In conclusion, there is no idle slot for the optimal solution to RUS-2SIC.
